

ECC006 - WEB DESIGN AND DEVELOPMENT

Homework Assignment #7

1. How would you link to the named fragment #jobs on the page employ.html from the home page of the site?
 - a. `<a href="employ.html#jobs">Jobs</a>`
2. Which pseudo-element can be used to generate content that precedes an element?
 - b. `:before`
3. Which of the following is a mobile web design best practice?
 - c. Configure a single-column page layout.
4. The page below is intended for the navigation area to display on the right side of the browser window. What needs to be changed to make this happen?

```
nav { float: left;
width: 120px; }
main { padding: 20px 150px 20px 20px;
background-color: #ffffff;
color: #000000; }
```

Answer.

To make the navigation area display on the right side instead of the left, two main changes need to be

applied in the CSS styles:

Change the float property of the nav element from `float: left;` to `float: right;`.

Adjust the padding of the main element to prevent the text from overlapping with the navigation bar.

The current padding creates a large space on the right (`padding: 20px 150px 20px 20px;`).

This should be changed to create space on the left instead: `padding: 20px 20px 20px 150px;`.

Web Research Summary

When designing modern websites, developers must ensure that the user experience is optimal for both mobile users and users with disabilities. Interestingly, there is a substantial amount of overlap between mobile web design best practices and universal web accessibility requirements. Rather than creating entirely separate deployment paradigms, web developers can adopt standards that simultaneously support both mobile device limitations and accessibility criteria.

A primary area of alignment is the handling of non-text elements, such as alternative text (alt text) for images. For visually impaired users relying on screen readers, descriptive alternative text is essential

to interpret graphical content. Concurrently, mobile users operating under constrained bandwidth conditions or slow internet connections frequently disable automatic image loading to optimize data consumption. In both scenarios, the precise implementation of alternative text satisfies independent needs using a single structural attribute.

Furthermore, page layout conventions represent another critical intersection. Mobile web optimization strongly favors a single-column architecture to accommodate limited screen real estate and

prevent horizontal scrolling. This streamlined, minimalist structural organization is highly beneficial for

individuals with cognitive or learning disabilities, as it minimizes visual distractions and establishes a predictable reading hierarchy. Similarly, the strategic use of semantic HTML headings (h1, h2, h3) facilitates rapid content scanning for mobile users while enabling assistive technologies to construct clear navigation trees for accessibility.

In conclusion, effective web development does not necessitate isolated strategies for mobile platforms and assistive compatibility. By prioritizing clean navigation structures, flexible single-column

layouts, structural heading hierarchies, and comprehensive text alternatives, web developers inherently

produce websites that deliver excellent usability to smartphone users and individuals with diverse accessibility needs alike.
